Flooring systems can also provide a decorative surface, a protection against water or other contaminants, or be used to isolate components of a building, such as a health care facility. Accordingly, the flooring systems in a building need to be durable and require minimal maintenance to insure the surface remains usable. In addition, because the flooring systems are used in a variety of different areas throughout a building and may be used to form walls, floors, ceilings, etc., the flooring system may be disposed in areas with significant amounts of heat (e.g., a building with a hot and humid environment or an air conditioning system). Typically, a synthetic flooring system may have a different density than a natural flooring system, which may make the synthetic flooring system more suitable for an area with a high heat level. However, the natural flooring systems may provide a substantially cool environment due to the natural insulation properties of the ground surface. Thus, it may be desirable to have a flooring system that can either insulate or dissipate heat, and is preferably both. Synthetic flooring systems have been developed that can provide the surfaces of the floor with a variety of different appearances or textures. These systems may include a floor base having an adhesive layer applied to a surface of a floor. One or more layers of a floor covering may be applied to the adhesive layer. Examples of floor covering materials that can be used in synthetic flooring systems are vinyl tile, ceramic tile, stone, and engineered wood flooring. The floor covering material may be installed over the adhesive layer, which bonds the floor covering material to the floor base. The floor covering material may have a specific thickness when installed. However, the thickness of a finished floor covering may vary over its useful life. For example, the floor covering material may be installed at a specific thickness. However, moisture may expand and contract the material, causing the thickness of the floor covering to change. As the thickness of the floor covering changes, the contact surface area of the floor covering changes. This may cause the performance of the floor covering to vary. Accordingly, it may be desirable to have a flooring system that provides a consistent visual appearance over its
